# Input modification

the amount of inputs it tries to change per attempt (aka iteration)

this is the timeframe in which bruteforce tries to change the inputs

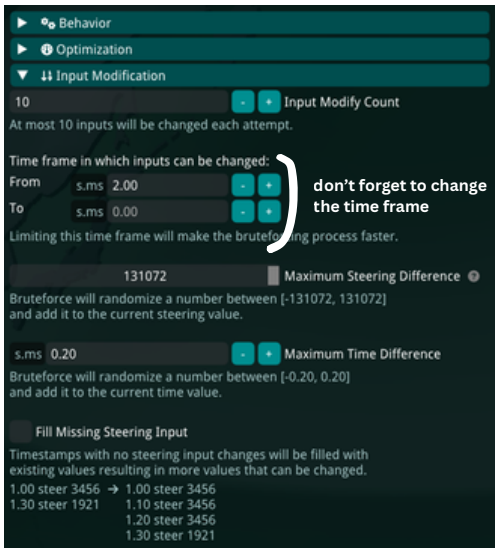

if this is set to 0.00 it will just automatically set it to the replay length

this is how much it can change the steering per attempt

this will change the timings of the inputs

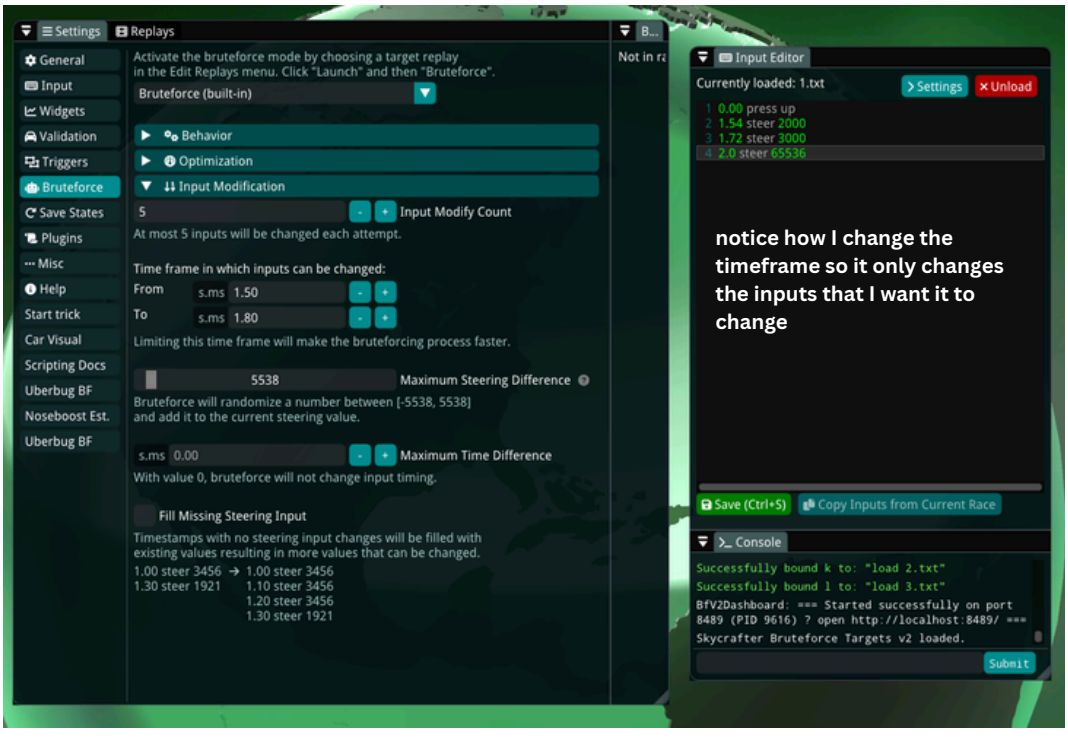

this just adds extra inputs (it's useful for noseboosts, ubers and very short sections but disabling it is better for most stuff)

explanation

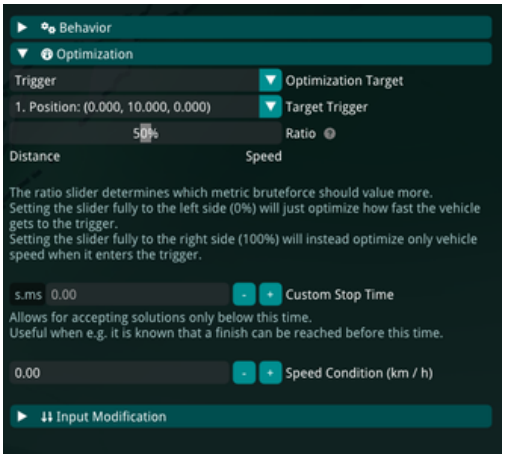

don't forget to change the time frame

**We will use this for most stuff**

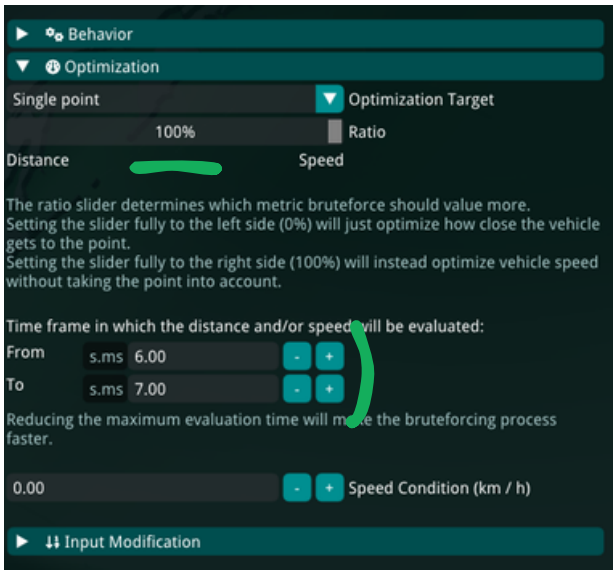

**I use this to perfect the precision**

# Optimization

the car will try to reach the red cube with good speed and time (50% is good most of the time)

we will use this most of the time

this is pretty much only used for ubers and noseboosts

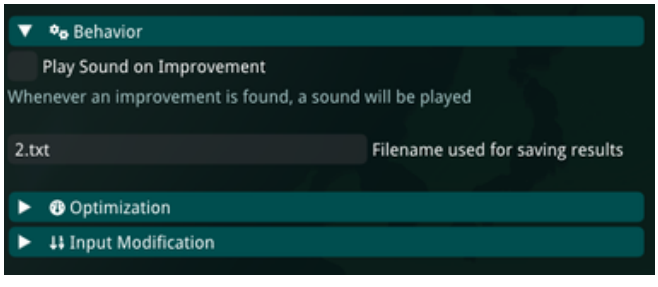

it just tries to get max speed in this timeframe

this is kind of advanced don't worry xdd
you do not need to be doing crazy ubers on day 1

when you get a fast uber or noseboost and you want it to go somewhere you use this. Go to the place you want the car to go with cam 8 (set the position) and also make sure that the time frame is big enough so the car can reach that point

you can also use this if there is a hard to reach place on a trial map for example

do not forget to change this so the inputs don't override if you are bfing multiple times
